**Abstract**

A study on drying cloves (*Syzygium aromaticum*) was conducted in Bogor, Indonesia, in November, 2008. The purpose of this study is to evaluate the performance of GHE-hybrid dryer applying greenhouse effect mechanism and biomass energy to improve drying air temperatures, and electricity to force the drying air. The GHE-hybrid dryer tested is a deep bed crop dryer represented by 10 series of thin layers covered by polycarbonate sheet. The dryer is supported by 2 axial fans and a biomass stove. The biomass stove is equipped by 99 baffles functioning as heat exchanger. For each drying batch of 1 cm thickness, the drying capacity is 144 kg of cloves. The temperature of drying air from the collector varied between 28 and 52°C and cloves could be dried in 42 hours (6 days) where drying process was run intermittence during the day. Drying chamber temperatures varied in average between 36 to 46°C. The different temperatures among 10 layers were from 3 to 12°C. Air velocity found in drying chamber was in range of 0.04 to 2.09 m s\(^{-1}\) by average of 0.68 m s\(^{-1}\). Thermal efficiency is found about 15\%, and drying efficiency is around 23\%. Based on the cloves initial moisture content of 71.32\%, the energy specific found was 16.79 MJ per kg of evaporated water. The energy input was dominated by the use of biomass energy (75\%) since the research was conducted during the beginning of rainy seasons. Solar energy contributed about 15\% and electricity shared about 10\%. It was estimated that due to the variation of temperatures, air velocity, and humidity in the drying chamber the final moisture content wet basis varied highly from 0.2\% to 19.2\%.

**Keywords:** Biomass energy, cloves, solar dryer, greenhouse effect
