"Fish and Shrimp as Resources for Livelihood Development of Coastal Fishing
 Communities in Egypt: DNA Barcoding Application in Fisheries Management,
 Marine Biodiversity Assessment, Management and Conservation"

RESULTS

Discussion

MATERIALS & METHODS

What the geneticist sees

$$Y_{ijk} = \mu + M_i + F_{ij} + \varepsilon_{ijk}$$

Families identified by markers

DNA marker-based pedigrees

It is technically possible to simultaneously select for growth and disease resistance in two environments (SPF and SPR) simultaneously.

Costs and pay-offs

type	start	gain	cost
on farm genetics	1 yr	5% - 10%	10 - 100 k€
centralized breeding facility (selection)	3 yr	5% - 10%	0.5 - 2 m\$
marker assisted selector	5+ yr	3% - 10%	0.1 - 2m\$
transgenics	1 - 10+ yr	200 - 400%	0.1 - 2m\$

Technology cost-price squeeze

What aquaculture geneticists do

Genetics options for growers

1. Join a big genetics program where many farmers share the benefits.
2. Professional on-farm private genetics.
3. Do-it-yourself (sophisticated amateur).
4. Buy the best commercial seed every year.
5. Common sense: breed the best animals.
6. Do nothing about genetics.

Strategies for genetic improvement

1. Insert additional plus genes (transgenics).
2. Hybridize, hoping that the offspring will exceed both parents.
3. Identify a plus allele and select individuals which are carrying it (QTL selection).
4. Select a gene which is close to the plus gene (marker assisted selection).
5. Select individuals based on their performance and/or performance of relatives.

ACKNOWLEDGEMENTS

We would like to thank all researchers participated in this project for their co-operation. This project received funding from the Science and Technology Development Fund (STDF).
